

Other Body Systems that work with the Excretory System

Circulatory: Blood passes through both of your kidneys, and it is filtered. Waste is taken out of it (Uric acid and urea) and is replaced with water.

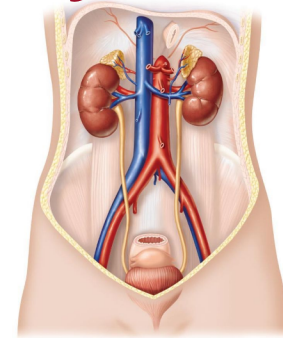

Endocrine: The major controller of the excretory system. Monitors the levels of fluid, which in turn control how the kidney's function. For example, when drinking a lot of water the kidney's to work more, and make more urine. It will also produces adrenals.

Parts of this system

Lungs: Allows you to dispose of any excess carbon dioxide in your body by breathing it out.

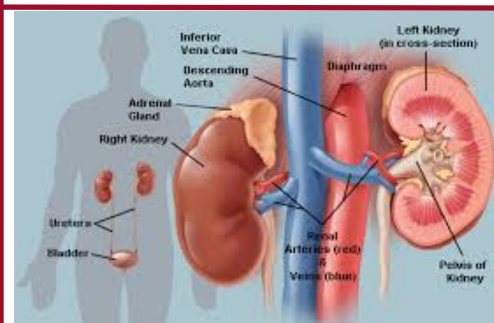

Sweat Glands: Disposes of any extra fluid, can cool body down.

Kidneys: The kidney's act as a filter to the blood. It takes out the acids and any other harmful chemicals.

Ureters/Urethra: Allows urine to leave the body

The Excretory System

The excretory system isn't the most pleasant of all the other systems. In fact, it's kinda like the garbage dump of the systems. It's used to dispose of all the waste your body creates, but it can also filter all the muck out of it.

What are the dangers

Malfunctioning Kidneys: When a kidney stops working, your blood pressure can increase to dangerous levels

Solutions:

Dialysis: It can act as an artificial kidney, as it will filter blood for you.

Most issues can be solved with a kidney transplant
